

# CHAPTER 47: ANIMAL DEVELOPMENT

AP Biology 2013

1

## ZYGOTE TO ADULT

- Preformation - 18th century theory that the egg or sperm contained an embryo

- The embryo was thought to be a preformed miniature infant (homunculus) that becomes larger during development

- We now know:

- An organism's development is determined by the genome of the zygote and by differences that arise between early embryonic cells

- Cell differentiation - specialization of cells in their structure and function

- Morphogenesis - process by which an animal takes shape

2

## DEVELOPMENTAL EVENTS

- Fertilization - main function is to bring the haploid nuclei of sperm and egg together to form a diploid zygote

- Contact of the sperm on the egg's surface initiates metabolic reactions within the egg that trigger embryonic development

- Acrosomal reaction - when sperm meets egg, hydrolytic enzymes that digest material surrounding the egg are released

- Gamete contact blocks polyspermy

Fig. 47.3

3

## DEVELOPMENTAL EVENTS

- Fertilization:

- Fusion of egg and sperm also initiates the cortical reaction which causes a rise in  $\text{Ca}^{2+}$  that stimulates cortical granules to release their contents outside the egg

- These changes cause the formation of a fertilization envelope that also acts as a block to polyspermy

Fig. 47.4

4

## DEVELOPMENTAL EVENTS

Fig. 47.5

- Activation of the Egg

- Because of the rise in  $\text{Ca}^{2+}$  in the egg's cytosol, the rate of cellular respiration and protein synthesis increases substantially

- In mammals, the cortical reaction modifies the zona pellucida as a slow block to polyspermy

5

## DEVELOPMENTAL EVENTS

- Cleavage - period of rapid cell division without growth

- Many animals (not mammals) have defined polarity (distribution of yolk with vegetal pole having the most and the animal pole having the least)

(a) Fertilized egg (b) Four-cell stage (c) Early blastula (d) Later blastula

Figs. 47.6

6

# DEVELOPMENTAL EVENTS

- Cleavage planes follow a specific pattern relative to the animal and vegetal poles

- Meroblastic cleavage - incomplete division of the egg (yolk-rich eggs like reptiles and birds)

- Holoblastic cleavage - complete division of the egg (little or moderate amounts of yolk like sea urchins and frogs)

Fig. 47.7

## DEVELOPMENTAL EVENTS

- Morphogenesis - cells occupy their appropriate locations
- Gastrulation - rearranges the cells of the blastula into a three-layered embryo called a gastrula that has a primitive gut

<b>ECTODERM (outer layer of embryo)</b>
<ul style="list-style-type: none"> <li>• Epidermis of skin and its derivatives (including sweat glands, hair follicles)</li> <li>• Nervous and sensory systems</li> <li>• Pituitary gland, adrenal medulla</li> <li>• Jaws and teeth</li> <li>• Germ cells</li> </ul>
<b>MESODERM (middle layer of embryo)</b>
<ul style="list-style-type: none"> <li>• Skeletal and muscular systems</li> <li>• Circulatory and lymphatic systems</li> <li>• Excretory and reproductive systems (except germ cells)</li> <li>• Dermis of skin</li> <li>• Adrenal cortex</li> </ul>
<b>ENDODERM (inner layer of embryo)</b>
<ul style="list-style-type: none"> <li>• Epithelial lining of digestive tract and associated organs (liver, pancreas)</li> <li>• Epithelial lining of respiratory, excretory, and reproductive tracts and ducts</li> <li>• Thymus, thyroid, and parathyroid glands</li> </ul>

Figs. 47.8-47.9

- Three embryonic germ layers:

- Ectoderm - outer layer of gastrula
- Endoderm - lines the embryonic digestive tract
- Mesoderm - partially fills the space between the ectoderm and endoderm

## GASTRULATION FROG VS. CHICK

Fig. 47.10

Fig. 47.11

# GASTRULATION IN HUMANS

- Human eggs have very little yolk
- Blastocyst - human equivalent of blastula
- Inner cell mass - cluster of cells at one end of the blastocyst
- Trophoblast - outer epithelial layer that does not contribute to embryo but instead initiates implantation
- Gastrulation

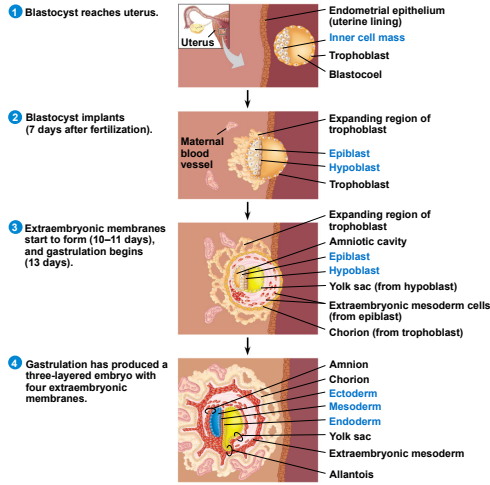

Fig. 47.12

10

# ORGANOGENESIS

- Regions of the three germ layers develop into the rudiments of organs during organogenesis
- Vertebrates form a notochord from the mesoderm and a neural plate from the ectoderm
- Neural plate curves inward forming the neural tube

Mesoderm also gives rise to the somites (later form vertebrae and muscle) and the coelom

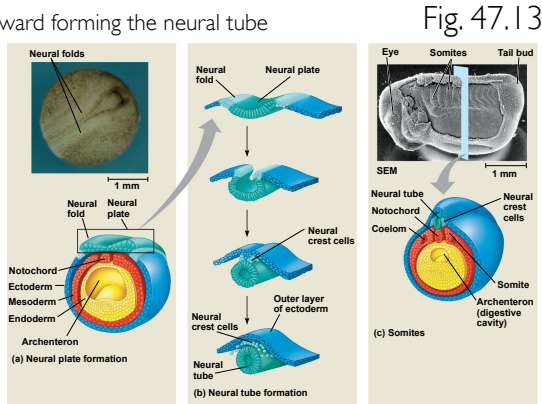

Fig. 47.13

11

# MORPHOGENESIS

- Involves changes in shape, position, and adhesion
- Changes in shape involve reorganization of the cytoskeleton
  - Formation of the neural tube involves microtubules and microfilaments
- Also impacts cell migration (movement of cells from one place to another) ex. convergent extension
- Tissue invagination is caused by changes in both cells shape and migration during gastrulation

Figs. 47.15 & 47.16

12

# MORPHOGENESIS

- Apoptosis - programmed cell death
- At various times during development, individual cells, sets of cells, or whole tissues stop developing and are engulfed by neighboring cells

13

# DEVELOPMENTAL FATE

- Determination - cell or group of cells becomes committed to a particular fate
- Differentiation
  - Embryonic cells must become different from on another
  - Interactions with other embryonic cells influence the fate of cells by causing changes in gene expression
- Fate maps - territorial diagrams of embryonic development

(a) Fate map of a frog embryo

(b) Cell lineage analysis in a tunicate

# AXES OF EMBRYOS

Figure 47.21

Figs. 47.21 & 47.22

# THE "ORGANIZER"

- Initiates a chain reaction of inductions that result in the formation of the notochord, neural tube, and other organs

- Plays a major role in pattern formation (spatial organization)

- Positional information tells a cell where it is with respect to the animal's body axes

- Wings and legs of chicks begin as limb buds

- Limb buds respond to positional information

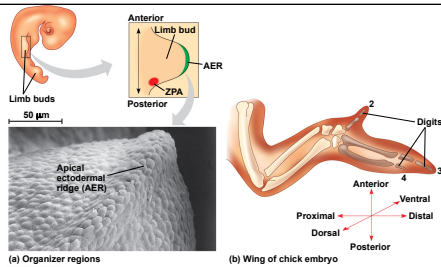

Fig. 47.24 & 47.25
